**alpha and beta decay practice problems with answers** provide an essential tool for students and professionals studying nuclear physics, helping to understand radioactive decay processes. Mastery of these types of decay is critical for fields such as nuclear medicine, energy production, and radiation safety. This article offers a comprehensive collection of practice problems focused on alpha and beta decay, each accompanied by detailed answers. These problems cover fundamental concepts like identifying decay products, calculating energy released, and applying decay equations. Additionally, explanations clarify the differences between alpha decay, beta-minus decay, and beta-plus decay, enhancing conceptual understanding. The practice problems are structured to build confidence and competence in solving typical radioactive decay scenarios. Readers will find this resource valuable for exam preparation, coursework, or self-study in nuclear chemistry and physics.

## Understanding Alpha and Beta Decay

Alpha and beta decay are two common types of radioactive decay that involve the emission of particles from unstable atomic nuclei. Alpha decay releases an alpha particle, which consists of two protons and two neutrons, effectively reducing the atomic number by two and the mass number by four. Beta decay involves the transformation of a neutron into a proton or vice versa and the emission of a beta particle, which can be either an electron (beta-minus) or a positron (beta-plus). Understanding these processes is crucial for solving decay problems accurately and predicting the resulting isotopes after decay. These concepts form the foundation of the following practice problems and their step-by-step solutions.

## Key Characteristics of Alpha Decay

Alpha decay is characterized by the emission of a helium nucleus (alpha particle) from a radioactive atom. This process typically occurs in heavy elements such as uranium and radium. The loss of an alpha particle decreases the parent nucleus's atomic number by two and the mass number by four, resulting in a new element with different chemical properties. Alpha particles have low penetration power but high ionizing capability, making them significant in radiation safety contexts.

## Key Characteristics of Beta Decay

Beta decay comes in two forms: beta-minus and beta-plus decay. In beta-minus decay, a neutron in the nucleus converts into a proton, emitting an electron and an antineutrino. In beta-plus decay, a proton converts into a neutron, emitting a positron and a neutrino. Beta decay changes the atomic number by one but leaves the mass number unchanged. These transformations allow unstable isotopes to move toward greater nuclear stability.

## Alpha Decay Practice Problems with Answers

Alpha decay problems typically involve determining the daughter nucleus after the emission of an alpha particle and calculating the changes in atomic and mass numbers. Below are several practice problems with detailed answers to reinforce understanding of alpha decay mechanics.

1.

**Problem:** Uranium-238 undergoes alpha decay. Write the nuclear equation and identify the daughter nucleus.

**Answer:** Uranium-238 has an atomic number of 92. Emitting an alpha particle (2 protons and 2 neutrons) reduces the atomic number by 2 and the mass number by 4. The daughter nucleus is Thorium-234.

Nuclear equation:  ${}^{238}_{92}\text{U} \rightarrow {}^{234}_{90}\text{Th} + {}^4_2\text{He}$ .

2.

**Problem:** Calculate the remaining mass of a 10-gram sample of Polonium-210 after 3 alpha decay half-lives, given its half-life is 138 days.

**Answer:** After 3 half-lives, the remaining mass is  $(1/2)^3$  of the original mass.

Remaining mass =  $10 \text{ g} \times (1/8) = 1.25 \text{ g}$ .

3.

**Problem:** Identify the new element formed when Radium-226 undergoes alpha decay.

**Answer:** Radium-226 (atomic number 88) loses an alpha particle.

New element: Radon-222 (atomic number 86).

Nuclear equation:  $^{226}_{88}\text{Ra} \rightarrow ^{222}_{86}\text{Rn} + ^4_2\text{He}$ .

## Beta Decay Practice Problems with Answers

Beta decay problems involve determining the daughter nucleus after beta emission and understanding the changes in atomic number. These examples illustrate typical beta decay scenarios and their solutions.

1.

**Problem:** Write the nuclear equation for the beta-minus decay of Carbon-14.

**Answer:** Carbon-14 (atomic number 6) emits a beta-minus particle (electron), converting a neutron to a proton. The daughter nucleus is Nitrogen-14 (atomic number 7).

Nuclear equation:  $^{14}_6\text{C} \rightarrow ^{14}_7\text{N} + \beta^- + \bar{\nu}_e$ .

2.

**Problem:** Explain what happens during beta-plus decay and provide the nuclear equation for Potassium-40 undergoing beta-plus decay.

**Answer:** Beta-plus decay occurs when a proton converts into a neutron, emitting a positron and a neutrino. For Potassium-40 (atomic number 19), the daughter nucleus is Argon-40 (atomic number 18).

Nuclear equation:  $^{40}_{19}\text{K} \rightarrow ^{40}_{18}\text{Ar} + \beta^+ + \nu_e$ .

3.

**Problem:** A sample of a beta-minus emitter has a half-life of 10 hours.

How much of a 20-gram sample remains after 30 hours?

**Answer:** After 3 half-lives (30 hours), the remaining mass is:

$$20 \text{ g} \times (1/2)^3 = 20 \text{ g} \times 1/8 = 2.5 \text{ g}.$$

## Mixed Decay Problems and Their Solutions

Some radioactive isotopes undergo multiple types of decay or decay chains involving both alpha and beta emissions. These problems require tracking sequential decay steps and predicting final products.

### Sequential Decay Problem

Consider the decay chain of Uranium-238, which undergoes alpha decay followed by beta decay steps. Solving these problems involves applying both alpha and beta decay principles in sequence.

1.

**Problem:** Uranium-238 undergoes alpha decay to Thorium-234, which then undergoes beta-minus decay. Write the nuclear equations for both steps and identify the final product.

**Answer:**

- Alpha decay:  ${}^{238}_{92}\text{U} \rightarrow {}^{234}_{90}\text{Th} + {}^4_2\text{He}$
- Beta-minus decay:  ${}^{234}_{90}\text{Th} \rightarrow {}^{234}_{91}\text{Pa} + \beta^- + \bar{\nu}_e$

The final product after these two decays is Protactinium-234.

### Problem Solving Strategies

When approaching mixed decay problems, it is important to carefully track changes in atomic and mass numbers after each decay step. Writing out nuclear equations clearly and verifying conservation of nucleons helps avoid mistakes. Understanding the nature of each decay type simplifies the identification of daughter isotopes.

# Tips for Solving Radioactive Decay Problems Effectively

Succeeding in alpha and beta decay practice problems with answers requires systematic problem-solving techniques. The following tips enhance accuracy and comprehension in radioactive decay calculations.

- **Memorize fundamental decay types:** Know the characteristics of alpha, beta-minus, and beta-plus decay to quickly predict daughter nuclei.
- **Use nuclear notation:** Write the full nuclear reaction with atomic and mass numbers to track changes precisely.
- **Calculate half-life decay:** Apply the half-life formula correctly to determine remaining quantities over time.
- **Check conservation laws:** Confirm that mass and atomic numbers balance on both sides of the equation.
- **Practice systematically:** Work through problems progressively, starting from simple decays to complex decay chains.

Consistent practice with alpha and beta decay problems improves understanding of nuclear transformations and prepares learners for advanced studies in nuclear chemistry and physics. The provided examples and strategies offer a solid framework for mastering these essential concepts.

## Frequently Asked Questions

### What is the difference between alpha decay and beta decay?

Alpha decay involves the emission of an alpha particle (2 protons and 2 neutrons), resulting in a decrease of the atomic number by 2 and mass number by 4. Beta decay involves the transformation of a neutron into a proton with the emission of a beta particle (electron or positron), changing the atomic number by  $\pm 1$  but leaving the mass number unchanged.

### How do you write the nuclear equation for alpha decay of Uranium-238?

Uranium-238 undergoes alpha decay by emitting an alpha particle (He-4 nucleus). The equation is:  ${}^{238}_{92}\text{U} \rightarrow {}^4_2\text{He} + {}^{234}_{90}\text{Th}$ . Here, the atomic number

decreases from 92 to 90, and the mass number decreases from 238 to 234.

## **What is the product nucleus when Carbon-14 undergoes beta decay?**

When Carbon-14 undergoes beta decay, a neutron is converted into a proton and an electron (beta particle) is emitted. The product nucleus is Nitrogen-14 (atomic number 7). The equation is:  $^{14}\text{C} \rightarrow ^{14}\text{N} + \beta^-$ .

## **How to balance the nuclear equation for beta plus decay (positron emission) of Potassium-40?**

In beta plus decay, a proton is converted into a neutron and a positron is emitted. For Potassium-40:  $^{40}\text{K} \rightarrow ^{40}\text{Ar} + \beta^+$ . The atomic number decreases from 19 to 18, mass number remains 40.

## **What practice problem can help understand the change in atomic and mass numbers during alpha decay?**

Practice Problem: Write the nuclear equation for the alpha decay of Radium-226. Answer:  $^{226}\text{Ra} \rightarrow ^4\text{He} + ^{222}\text{Rn}$ . Atomic number decreases by 2 (from 88 to 86), mass number decreases by 4 (from 226 to 222).

## **How to determine the missing particle in a beta decay equation?**

Given a beta decay equation with a missing particle, use conservation of atomic and mass numbers. For beta minus decay, the atomic number of the product is one more than the parent, mass number stays the same, and the emitted particle is an electron ( $\beta^-$ ). For beta plus decay, atomic number decreases by one, mass number stays the same, and the emitted particle is a positron ( $\beta^+$ ).

## **Can you provide a sample alpha decay problem with solution?**

Problem: Polonium-210 undergoes alpha decay. Write the nuclear equation and identify the daughter nucleus. Solution:  $^{210}\text{Po} \rightarrow ^4\text{He} + ^{206}\text{Pb}$ . The daughter nucleus is Lead-206 with atomic number 82.
