Understanding Age Regression

Age regression is a psychological state in which an individual reverts to a younger age mentally and emotionally. This state can manifest spontaneously or be intentionally induced as a coping mechanism to deal with stress, trauma, or anxiety. While age regression is often misunderstood, it is a recognized phenomenon within both clinical and non-clinical contexts.

The Psychology Behind Age Regression

Psychologists describe age regression as a defense mechanism where the mind retreats to a developmental stage that feels safer or less stressful. It can be triggered by external stressors or internal emotional conflicts. In therapy, age regression may be used to revisit childhood experiences for healing purposes.

Types of Age Regression

Age regression can be categorized into two main types: spontaneous and intentional. Spontaneous
